## **CRISPR/Cas9-generated p47phox-deficient cell line for chronic granulomatous disease gene therapy vector development**

Wrona, Dominik ; Siler, Ulrich ; Reichenbach, Janine

**Abstract:** Development of gene therapy vectors requires cellular models reflecting the genetic background of a disease thus allowing for robust preclinical vector testing. For human p47phox-deficient chronic granulomatous disease (CGD) vector testing we generated a cellular model using clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 to introduce a GT-dinucleotide deletion ( $\Delta$ GT) mutation in p47phox encoding NCF1 gene in the human acute myeloid leukemia PLB-985 cell line. CGD is a group of hereditary immunodeficiencies characterized by impaired respiratory burst activity in phagocytes due to a defective phagocytic nicotinamide adenine dinucleotide phosphate (NADPH) oxidase. In Western countries autosomal-recessive p47phox-subunit deficiency represents the second largest CGD patient cohort with unique genetics, as the vast majority of p47phox CGD patients carries  $\Delta$ GT deletion in exon two of the NCF1 gene. The established PLB-985 NCF1  $\Delta$ GT cell line reflects the most frequent form of p47phox-deficient CGD genetically and functionally. It can be differentiated to granulocytes efficiently, what creates an attractive alternative to currently used iPSC models for rapid testing of novel gene therapy approaches.

Development of gene therapy vectors requires cellular models reflecting the genetic background of a disease thus allowing for robust preclinical vector testing. For human p47<sup>phox</sup>-deficient chronic granulomatous disease (CGD) vector testing we generated a cellular model using clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 to introduce a GT-dinucleotide deletion ( $\Delta$ GT) mutation in p47<sup>phox</sup> encoding *NCF1* gene in the human acute myeloid leukemia PLB-985 cell line. CGD is a group of hereditary immunodeficiencies characterized by impaired respiratory burst activity in phagocytes due to a defective phagocytic nicotinamide adenine dinucleotide phosphate (NADPH) oxidase. In Western countries autosomal-recessive p47<sup>phox</sup>-subunit deficiency represents the second largest CGD patient cohort with unique genetics, as the vast majority of p47<sup>phox</sup> CGD patients carries  $\Delta$ GT deletion in exon two of the *NCF1* gene. The established PLB-985 *NCF1*  $\Delta$ GT cell line reflects the most frequent form of p47<sup>phox</sup>-deficient CGD genetically and functionally. It can be differentiated to granulocytes efficiently, what creates an attractive alternative to currently used iPSC models for rapid testing of novel gene therapy approaches.

Chronic Granulomatous Disease (CGD) comprises a group of monogenetic immunodeficiencies characterized by impaired respiratory burst activity and microbicidal activity of phagocytes leading to recurrent life-threatening infections<sup>1</sup>. CGD can be cured by hematopoietic stem cell transplantation (HSCT)<sup>2</sup>. Alternatively, autologous retroviral gene therapy has been used in selected patients with X-linked CGD (X-CGD)<sup>3–7</sup>.

Mutations in gp91<sup>phox</sup>, p47<sup>phox</sup>, p67<sup>phox</sup>, p40<sup>phox</sup> or p22<sup>phox</sup> subunits of the phagocytic nicotinamide adenine dinucleotide phosphate (NADPH) oxidase may cause CGD<sup>8</sup>. In Western countries gp91<sup>phox</sup>-deficiency is the most frequent form (65%)<sup>9</sup>, followed by p47<sup>phox</sup>-deficiency (25%). Mutations within gp91<sup>phox</sup> are scattered throughout the whole cytochrome b-245 beta chain (*CYBB*) gene. Conversely, p47<sup>phox</sup>-deficiency is almost exclusively caused by a single GT-dinucleotide deletion ( $\Delta$ GT) in exon 2 of neutrophil cytosolic factor 1 (*NCF1*) gene causing frameshift and premature translation stop. The  $\Delta$ GT deletion is shared with two pseudogenes, *NCF1B* and *NCF1C*, all located on the same chromosome sharing extraordinary homology (99.5%) (Fig. 1A,B). Presumably, homologous recombination causes the predominance of the  $\Delta$ GT mutation in p47<sup>phox</sup>-deficient CGD patients<sup>10</sup>.

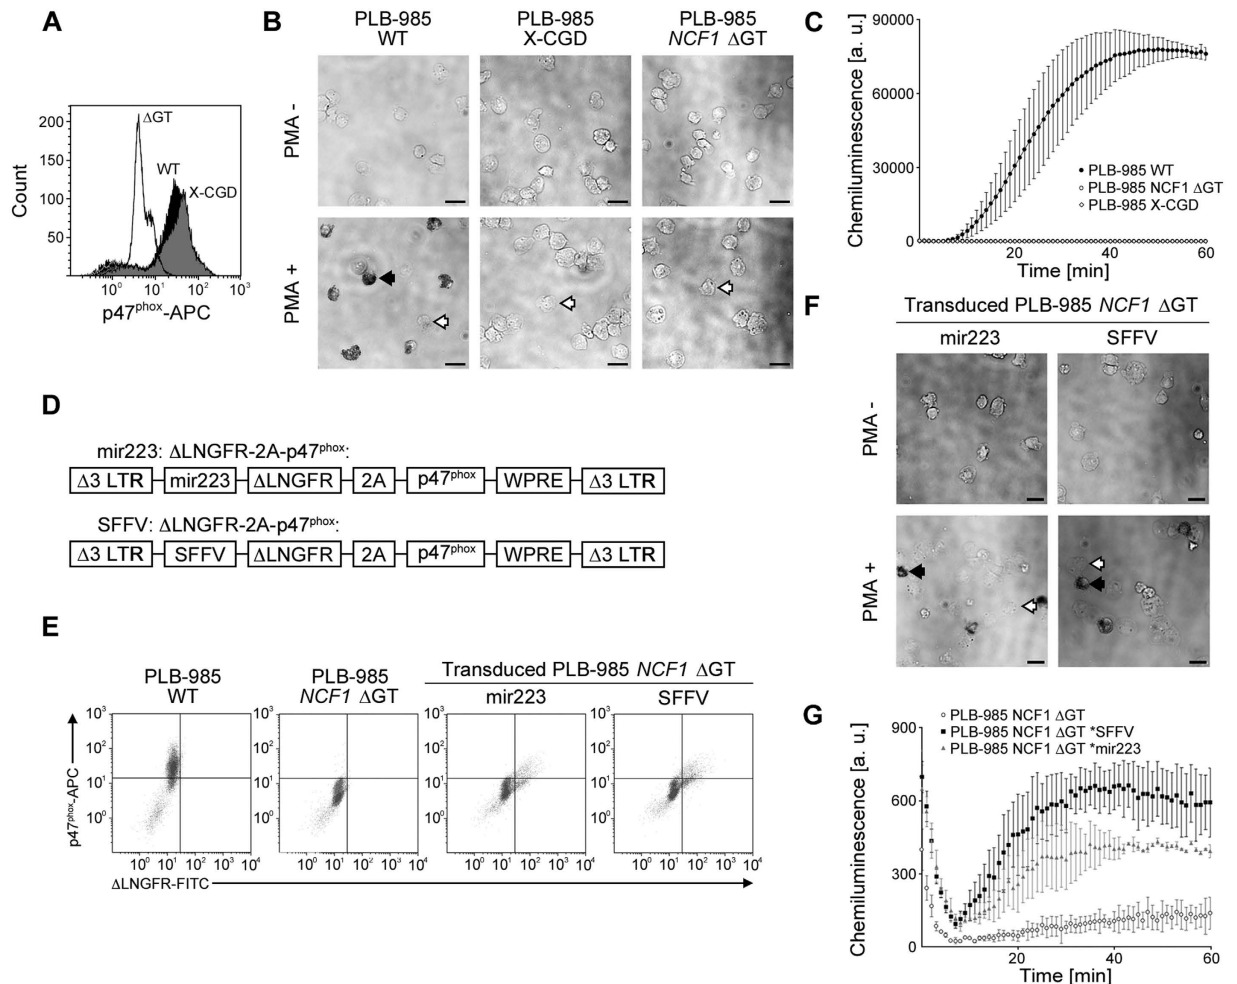

Currently, development of gene therapy vectors for p47<sup>phox</sup>-deficient CGD is hampered by the absence of human cell lines for rapid gene therapy vector testing. p47<sup>phox</sup>–/– mouse models exist, but cannot replace vector testing on human cells. Recently, we established human p47<sup>phox</sup>-deficient induced pluripotent stem cell (iPSC) lines harboring the  $\Delta$ GT within the *NCF1* gene<sup>11</sup>. Only these iPSC-based cell lines reflect the genetic background of the most frequent mutation in CGD. As maintenance and differentiation of iPSC lines is laborious and in many aspects impractical, we established a novel model for  $\Delta$ GT p47<sup>phox</sup>-deficient CGD based on a human acute myeloid leukemia PLB-985 cell line<sup>12</sup>.

We nucleofected PLB-985 wild type (WT) cells with pPX458-*NCF1* plasmid encoding Cas9, single guide RNA (sgRNA) targeting *NCF1*, and GFP. To introduce the  $\Delta$ GT in *NCF1* a 100-nucleotide long single stranded oligonucleotide (ssODN) template, carrying the  $\Delta$ GT, was co-transfected (Fig. 1C).

To confirm that differentiated PLB-985 *NCF1*  $\Delta$ GT cells mirror the absent respiratory burst observed in primary neutrophils of  $\Delta$ GT p47<sup>phox</sup>-deficient CGD patients, we tested this cell line for NADPH oxidase-mediated superoxide production with nitroblue tetrazolium (NBT) test. In differentiated PLB-985 WT cells, phorbol-12-myristate-13-acetate (PMA)-stimulation induced superoxide production in  $47.8 \pm 4.2\%$  of cells, as was visualized by formazan precipitates (Fig. 2B and Supplementary Fig. S5). In contrast, PMA-stimulation of differentiated

**Figure 2. Superoxide production in PLB-985 *NCF1* ΔGT.** (A) p47<sup>phox</sup> flow cytometry analysis and (B) ROS production in granuloctically differentiated PLB-985, PLB-985 X-CGD and PLB-985 *NCF1* ΔGT cells measured by NBT test. NBT-positive: black arrow; NBT-negative: white arrows. Scale bar: 25 μm. (C) Chemiluminescence assay of un-transduced PLB-985 WT, PLB-985 *NCF1* ΔGT, and PLB-985 X-CGD cell line (mean and standard deviation of mean, n = 3, a.u. = arbitrary units). (D) γ-retroviral vectors for reconstitution of p47<sup>phox</sup> expression. (E) Flow cytometry analysis of p47<sup>phox</sup> and ΔLNGFR expression in differentiated un-transduced PLB-985 WT and PLB-985 *NCF1* ΔGT, and transduced PLB-985 *NCF1* ΔGT cells. (F) ROS production in transduced PLB-985 *NCF1* ΔGT cells upon differentiation, measured by NBT test. NBT-positive: black arrow; NBT-negative: white arrows. Scale bar: 25 μm. (G) Chemiluminescence assay of transduced PLB-985 *NCF1* ΔGT cells (mean and standard deviation of mean, n = 3).

PLB-985 X-CGD and PLB-985 *NCF1* ΔGT cells resulted only in background signal of  $1.7 \pm 1.0\%$  and  $0.9 \pm 0.5\%$ . These results indicate that the established p47<sup>phox</sup>-deficient PLB-985 *NCF1* ΔGT cell line does not respond to PMA-stimulation by reactive oxygen species (ROS) production. The absence of ROS production in PLB-985 X-CGD and PLB-985 *NCF1* ΔGT cells was confirmed by chemiluminescence assay (Fig. 2C).

The iPSC model of ΔGT p47<sup>phox</sup>-deficient CGD<sup>11</sup> can be differentiated to monocytes, macrophages<sup>11</sup> and granulocytes<sup>15,16</sup>. Nevertheless, the use of iPSCs is laborious, and time-consuming, as phagocytic differentiation requires long culture periods of 35–43 days<sup>15,17</sup> requiring large amounts of cytokines and continuous surveillance of the culture. In contrast full granulocytic differentiation of PLB-985 *NCF1* ΔGT cell line takes 7 days, requires only fetal calf serum (FCS) restriction (5%) and supplementation with 0.5% N,N-dimethylformamide (DMF). Furthermore, the differentiation of neutrophils can be easily assessed by flow cytometry (Supplementary Fig. S3).

The function of the NADPH oxidase complex within PLB-985 *NCF1* ΔGT cells was reconstituted by transduction with two γ-retroviral vectors encoding p47<sup>phox</sup> protein (Fig. 2D). Transgene expression was driven either by the ubiquitously active spleen focus-forming virus (SFFV) promoter or by the myeloid-specific microRNA 223 (mir223) promoter<sup>18</sup>. The expression cassette was composed of truncated Low-affinity nerve growth factor receptor (ΔLNGFR) and p47<sup>phox</sup> linked by the 2A self-cleaving peptide<sup>19</sup>. Transduction efficiency reached 8.9% and 11.6% for mir223, and SFFV-driven γ-retroviral vectors (Fig. 2E).

Functional reconstruction of the NADPH oxidase complex activity in transduced and differentiated PLB-985 *NCF1*  $\Delta$ GT cells was assessed by NBT assay (Fig. 2F) and chemiluminescence assay (Fig. 2G). Percentage of NBT-positive cells reached  $13.4 \pm 2.1\%$  with the mir223, and  $11.8 \pm 1.8\%$  with the SFFV-driven  $\Delta$ LNGFR-2A-p47<sup>phox</sup> expression constructs (Fig. 2F and Supplementary Fig. S5). Chemiluminescence assay of transduced and differentiated PLB-985 *NCF1*  $\Delta$ GT cells confirmed reconstitution of ROS production. These results clearly indicate that the defect of the NADPH oxidase complex caused by the  $\Delta$ GT mutation within *NCF1* in the PLB-985 *NCF1*  $\Delta$ GT cell line can be corrected.

In summary, the CRISPR/Cas9-generated PLB-985 *NCF1*  $\Delta$ GT cell line fully recapitulates the genetic background and functional NADPH oxidase defect found in majority of p47<sup>phox</sup>-deficient CGD patients, can be corrected genetically and differentiated into functional neutrophils. The PLB-985 *NCF1*  $\Delta$ GT cell line therefore represents a promising cost-effective tool for rapid gene therapy vector testing.

## Materials and Methods

**Reagents and antibodies.** Single stranded DNA was purchased from Microsynth (Balgach, Switzerland). RPMI 1640 medium with stable glutamine and fetal calf serum (FCS) were purchased from PAN-Biotech (Aidenbach, Germany). Penicillin/streptomycin, Phusion High-Fidelity DNA Polymerase, and dNTPs were obtained from Thermo Fisher (Reinach, Switzerland), SCR7 was from Biovision (Milpitas, CA). BsrG1 was derived from New England Biolabs (Frankfurt/Main, Germany). N,N-dimethylformamide (DMF), propidium iodide (PI) and nitro blue tetrazolium (NBT) were obtained from Sigma Aldrich (Buchs, Switzerland). Mouse anti-human  $\Delta$ LNGFR monoclonal antibody, clone ME20.4-1.H4, fluorescein isothiocyanate (FITC)-conjugated was purchased from Miltenyi Biotec (Bergisch Gladbach, Germany), and mouse anti-human p47<sup>phox</sup> monoclonal antibody clone 1 was allophycocyanin (APC)-conjugated by Becton Dickinson AG (Allschwil, Switzerland). PE-Cy7-conjugated anti-mouse/human CD11b antibody was from BioLegend (Fell, Germany). Mouse anti-human CD15 FITC (Catalog no 347423) and mouse anti-human CD14 FITC (Catalog no. 345784) were from Beckton Dickinson AG (Allschwil, Switzerland). Mouse anti-Flavocytochrome b558 (human)-FITC clone 7D5 recognizing gp91<sup>phox</sup> was from LabForce AG (Muttens, Switzerland).

**Plasmid preparation.** The sgRNA sequence targeting the *NCF1* gene (but not *NCF1B* and *NCF1C* pseudogenes) was designed using Optimized CRISPR Design (<http://crispr.mit.edu>, F. Zhang laboratory, MIT 2015). Guide sequence CCCCCAGGTGTACATGTTCC was cloned into pSpCas9(BB)-2A-GFP (PX458) (F. Zhang, Addgene plasmid #48138)<sup>20</sup> to generate pPX458-*NCF1*, which was confirmed by sequencing (Microsynth).

**Cell culture and differentiation.** We utilized PLB-985 cell line<sup>12</sup>, a subclone of HL-60<sup>21,22</sup>, as it is capable of granulocytic differentiation. Cells were cultured in RPMI 1640 medium supplemented with 10% (vol/vol) FCS, and 1% (vol/vol) penicillin/streptomycin in a humidified incubator at 37 °C and 5% CO<sub>2</sub>. Granulocytic differentiation of logarithmically growing PLB-985 cells at density of  $0.8 \cdot 10^6$  cells/mL was induced by reduction of the FCS content to 5%, and supplementation with 0.5% (vol/vol) DMF. After 3 days, an equivalent of initial volume of differentiating medium was added and the differentiation continued until day 7.

**CRISPR/Cas9 mediated generation of PLB-985 *NCF1*  $\Delta$ GT cell line.**  $2 \cdot 10^6$  PLB-985 wild type (WT) cells were nucleofected (Amaza Cell Nucleofector Kit V and Amaza Nucleofector II, program C-023 (Lonza, Basel, Switzerland)) with 40  $\mu$ g of the pPX458-*NCF1* and a 100-nucleotide long ssODN sequence at final concentration 3  $\mu$ M. The sequence of the ssODN was: GCC TCT TTG GAG GCT GAA TGG GGT CCC CCG ACT CTG GCT TTC CCC CAG GTA CAT GTT CCT GGT GAA ATG GCA GGA CCT GTC GGA GAA GGT GGT CTA CCG G. Immediately after nucleofection 500  $\mu$ L of medium was added to the cuvette and the cells were incubated at room temperature for 10 minutes, transferred to 10 mL medium, then cultured for 48 hours. Additionally, the culture was supplemented with 1  $\mu$ M SCR7 starting 3–4 hours post nucleofection. After 48 hours GFP expressing cells were sorted with FACS Aria III FCF (Becton Dickinson AG, Allschwil, Switzerland) into single wells with 100  $\mu$ L of pre-conditioned, sterile filtered medium supplemented with 1  $\mu$ M SCR7.

**DNA Amplification and Restriction Fragment Length Polymorphism Analysis.** Processing of human samples is covered by ethical vote KEK ZH nr. 2015/0135. Genomic DNA was isolated using DNeasy Blood & Tissue Kit (Qiagen, Hombrechtikon, Switzerland). Parallel PCR co-amplification of the *NCF1*, *NCF1B*, and *NCF1C* was performed using published primers<sup>23</sup> (Fwd1 and Rev1, Fig. 1B). For PCR reaction using Fwd1/Rev2 primers Fwd1 primer was barcoded for each template producing products of 417 bp from *NCF1* and of 435 bp from *NCF1B* and *NCF1C*. PCR products were pooled for SMRT sequencing and analyzed according to barcode identities.

The PCR mixture included HF 10 $\times$  buffer, 200  $\mu$ M of each dNTP, 240 nM of each primer, 0.04 U/ $\mu$ L of Phusion High-Fidelity DNA Polymerase, and 2.5 ng/ $\mu$ L of genomic DNA. Initial denaturation at 95 °C for 3 minutes was followed by 36 cycles of denaturation (95 °C, 30 seconds), annealing (70 °C, 30 seconds), elongation (72 °C, 8 seconds), and a final elongation step (72 °C, 1 minute). PCR products were digested with BsrG1 and visualized on a 3% (w/vol) agarose gel.

**Single molecule real-time (SMRT) sequencing.** The *NCF1* gene and *NCF1B* and *NCF1C* pseudogenes were PCR amplified in parallel utilizing primers Fwd1 and Rev2 (Fig. 1B)<sup>23</sup>. The primer Fwd1 was barcoded for each FACS sorted clone and obtained PCR products were of 417 bp for *NCF1* and 435 bp for *NCF1B* and *NCF1C* templates. PCR reaction consisted of initial denaturation (95 °C, 3 minutes), 40 cycles of denaturation (95 °C, 30 seconds), annealing (60 °C, 30 seconds), elongation (72 °C, 30 seconds), and a final elongation step (72 °C, 3 minutes). PCR products were gel purified using QIAquick Gel Purification Kit (Qiagen). 10–20 ng of gel-purified PCR products were pooled and analyzed by SMRT sequencing by Functional Genomics Center

Zurich, ETH/University of Zurich, Zurich, Switzerland. Briefly, DNA amplicon library was produced using DNA Template Prep Kit 1.0 (Pacific Biosciences, Menlo Park, California, United States). The input DNA concentration and quality was measured using Qubit Fluorometer dsDNA Broad Range assay (Life Technologies, Zug, Switzerland) and Bioanalyzer 2100 12 K DNA Chip assay (Agilent Technologies AG, Basel, Switzerland). The SMRT bell template was prepared by end-repair of the DNA amplicons, followed by blunt-end ligation of overhang adapters and exonuclease treatment. The SMRT bell template was complexed with polymerase using P6 DNA/Polymerase Binding Kit 2.0 (Pacific Biosciences) according to the manufacturer's instructions. The samples were sequenced using Pacific Biosciences RS2 platform. From the raw reads, high quality circular consensus reads (CCS) were obtained through the Reads Of Insert protocol available in the SMRT Analysis suite (Pacific Biosystems). CCS reads were then de-multiplexed by exact matching of the sample barcodes, starting at the base immediately preceding the Fwd1 primer sequence. Reads with a length between 400 and 450 nucleotides were retained and matched against the *NCF1* reference sequence using blast<sup>24</sup>.

**Surveyor Assay.** Off-target sites were predicted utilizing the Optimized CRISPR Design (<http://crispr.mit.edu>, F. Zhang laboratory, MIT 2015). Loci of predicted sites (see Supplementary Table S2) were PCR amplified from gDNA of PLB-985 WT and PLB-985 *NCF1* ΔGT cells. Corresponding PCR amplification products were mixed in a ratio of 1:1, while PCR amplification product of PLB-985 WT was used as a control. The samples were denatured at 95 °C for 10 minutes, slowly renatured, and digested using Surveyor<sup>®</sup> Mutation Detection Kit For Standard Gel Electrophoresis (Integrated DNA Technologies, Leuven, Belgium) according to the manufacturer's instructions.

**Data Availability.** All SMRT sequencing data can be obtained upon request.

**Virus production and transduction.** Viruses were produced as described previously<sup>19</sup>. In brief, 293T cells were co-transfected with pUMVC, pMD2.VSV.G and γSIN-SFFV-ΔLNGFR-2A-p47<sup>phox</sup><sup>19</sup> or γSIN-miR223-ΔLNGFR-2A-p47<sup>phox</sup><sup>18</sup> in presence of 10 mM chloroquine. Sterile filtered virus containing supernatants were concentrated using Amicon-15 centrifugal filter devices with 100 kDa cutoff and stored at −80 °C until use.

PLB-985 *NCF1* ΔGT cells were γ-retrovirally transduced with vectors co-encoding p47<sup>phox</sup> protein and low-affinity nerve growth factor receptor (ΔLNGFR)<sup>18,19</sup> at concentration of 0.8·10<sup>6</sup> cells/mL, at multiplicity of infection (MOI) = 5, and in presence of 8 μg/mL protamine sulfate by spinoculation at 1286 g, 32 °C for 90 minutes, followed by incubation at 37 °C and 5% CO<sub>2</sub> for 24 hours. Then, cells were differentiated into granulocytes in presence of 0.5% DMF and 5% FCS for 6 days and analyzed thereafter.

**Flow cytometry analysis.** ΔLNGFR surface staining was carried out with 6 μL of mouse anti-LNGFR-FITC (Miltenyi Biotec) per 5 × 10<sup>5</sup> cells in 100 μL for 20 minutes, followed by washing in PBS. Intracellular staining of p47<sup>phox</sup> was conducted utilizing 360 ng of mouse anti-p47<sup>phox</sup>-APC (clone 1) per 5 × 10<sup>5</sup> cells in 100 μL and the IntraCell Kit (Immunostep, Salamanca, Spain) according to the manufacturer's instructions. Flow cytometry analysis was performed using a Gallios Flow Cytometer (Beckman Coulter).

**Nitroblue-tetrazolium (NBT) test.** Differentiated PLB-985 WT, PLB-985 X-CGD, and PLB-985 *NCF1* ΔGT cells, as well as transduced PLB-985 *NCF1* ΔGT cells were incubated in growth medium supplemented with 100 μg/mL NBT in the presence of 200 ng/mL PMA at 37 °C and 5% CO<sub>2</sub> for 30 minutes. Subsequently, the cells were fixed in 1% (vol/vol) formaldehyde. 250 cells per cytospin slide were analyzed manually for NBT activity using a Leica DM IL Fluo light microscope equipped with a DFC420 digital camera and LEICA application suite acquisition software (Leica Microsystems AG, Glattbrugg, Switzerland).

**Chemiluminescence assay.** Chemiluminescence assay on differentiated PLB-985 WT, PLB-985 X-CGD, and PLB-985 *NCF1* ΔGT cells, as well as transduced PLB-985 *NCF1* ΔGT was conducted in 96-well plate format at a cell density of 1 × 10<sup>5</sup> cells/200 ml in a Mithras LB 940 Luminometer (Berthold Technologies GmbH, Zug, Switzerland) as described recently<sup>11</sup>.

## Acknowledgements

We thank the Functional Genomics Center Zurich for SMRT sequencing, and Giancarlo Russo for SMRT sequencing data analysis. The study was supported by The CGD Society (grant no. CGDS16/01), EU-FP7 CELL-PID HEALTH-2010-261387, EU-FP7 NET4CGD, Fondazione Ettore e Valeria Rossi foundation, Gebert R f Stiftung, program “Rare Diseases–New Approaches” (grant no. GRS-046/10), the Gottfried und Julia Bangerter-Rhyner-Stiftung, Hochspezialisierte Medizin Schwerpunkt Immunologie (HSM-2-Immunologie) and by ZIHP (Zurich Center for Integrative Human Physiology),

## Author Contributions

D.W. and U.S. performed experiments, analyzed results and made the figures; D.W., U.S. and J.R. conceived and designed experiments and wrote the manuscript.
